GitHub and Git:

You can use Git to collaborate on work.

What is GitHub?

Is a cloud-based platform where you can store, share, and work together with others to write code. You can achieve this by storing your code in a "repository" on GitHub allows you to:

- "Show case or Share your work.
- "Track and manage" changes in your code overtime.
- Let others "review" your code, and make suggestions to improve it.
- "Collaborate" on a shared project, without worrying that your changes will impact the work of your collaborators before you're ready to integrate them.

#Collaborative working, one of GitHub's fundamental features, is made possible by the open-source software, Git, upon witch GitHub is built.

- ❖ So what is Git:
  Is a version control system that intelligently tracks changes in files-Git is particularly useful when you and a group of people are all making changes to the same files at the same time.
- ➢ Git commands:
  1- Git add:
  The git add command. Tells Git that you want to include updates to a particular file in the next commit.
  Exp:
  ```
  git add hello.py
  git commit
  ```
  2- Git branch: This command is your general –purpose branch administration tool. Lets you create isolated development environments within a single repository , git branch command lets you create, list , rename , and delete branches . It's doesn't let you switch between branches or put a forked history back together again. For this reason git branch is tightly integrated with git checkout and git merge commands.
  Exp:
  ```
  git branch crazy-experment
  ```

3- Git checkout: git checkout command operates upon three distinct entities: files, commits , and branches. Also this command lets you navigate between the branches created by git branch.

   Exp:

   $ > git branch

   Main

   Another-branch

   Feature-inprogress-branch

   $ > git checkout feature-inprogress-branch

4- Git clone: creates a copy of an existing Git repository cloning is the most common way for developers to obtain a working copy of a central repository.

5- Git commit: Takes the staged snapshot and commits it to the project history. Combined with git add, this defines that basic workflow for all Git users.

6- Git push: changes to your remote repository.
   Exp:
   Git push <remote_name>

7- Git status: List the status of the files you've changed and those you still need to add or commit.
   Exp:
   git status

8- Git delete: delete the feature branch/bookmark.
   Exp:
   git branch –d
   <branch_name>
